

Executive Statement

The reminder increased completion, although the week-four uplift is not enough to rule out a novelty effect.

Hypothesis and context

Experiment E-26-041 · eligible new accounts · randomized 1:1 · four weeks
· 12,804 assigned · conversion measured within 7 days.

Completion · control to treatment

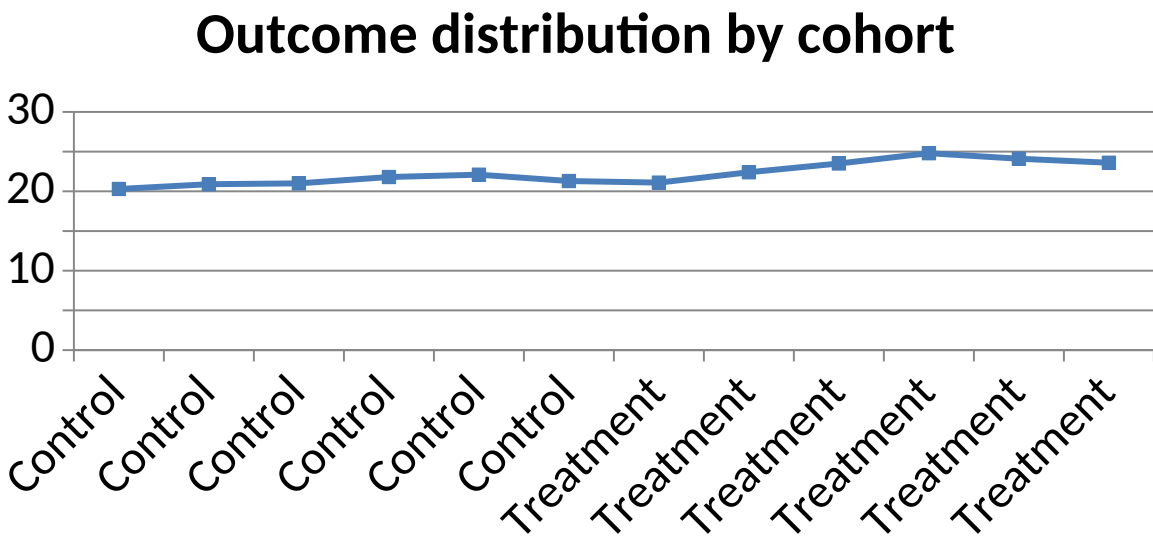

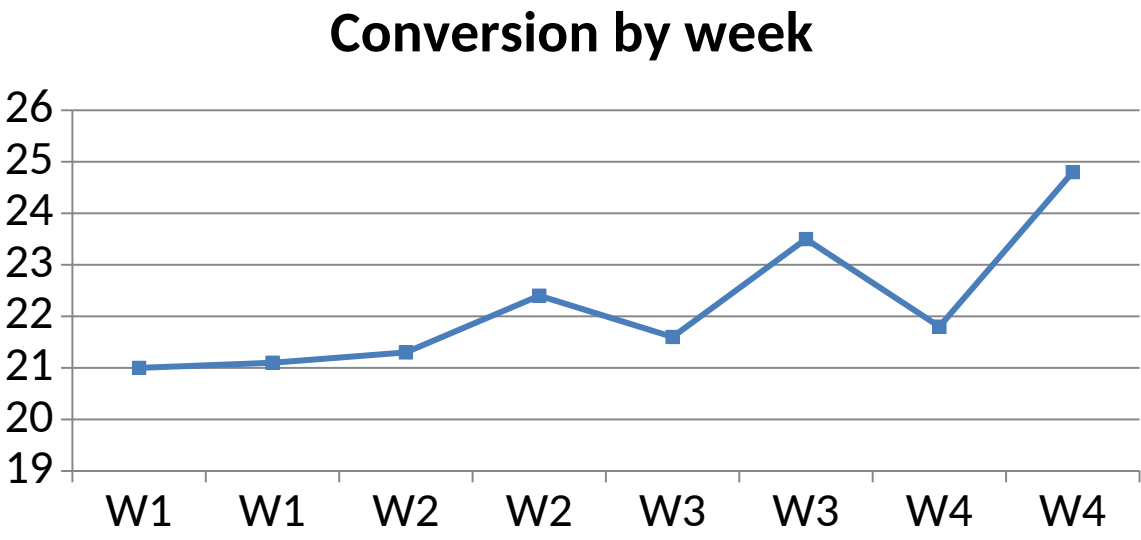

21.8% → 24.8%

Treatment completion

24.8%

Interpretation

Treatment completion rose from 21.1% to 24.8%; control moved from 21.0% to 21.8%. The observed separation is consistent across four weeks, while the support-contact guardrail moved by +0.08 points against a +0.15 limit. This descriptive comparison does not prove the effect will persist after the novelty period.

Cohort	Assigned	Completion	Support-contact change
Control	6402	21.8%	+0.00 pt
Treatment	6402	24.8%	+0.08 pt
Eligible holdout	1104	21.5%	No post-assignment exclusion

Recommendation

Extend to 25% exposure with a support-contact stop

The four-week signal is promising but does not establish persistence. Stop if support-contact change exceeds +0.15 points.

Limited rollout
